

## Obstructive Sleep Apnea ♦♦♦

Obstructive Sleep Apnea (OSA) occurs when the tongue and soft palate collapse onto the back of the throat. This blocks the upper airway causing air flow to stop. When the oxygen level drops low enough the brain moves out of deep sleep and the individual partially awakens. The airway then contracts and opens causing the obstruction in the throat to clear. The flow of air starts again usually with a loud gasp. When the air flow starts again you then move back into a deep sleep. The airway muscles collapse, as you awaken with a gasp. The airway clears once again as the process repeats itself. This scenario may occur many times during the night. The combination of low oxygen levels and fragmented sleep are the major contributors to most of the ill effects that the sleep apnea patient suffers. In addition to excessive daytime sleepiness studies show that sleep apnea patients are much more likely to suffer from heart problems (heart attack, congestive heart failure, hypertension), strokes, as well as having a higher incidence of work related and driving related accidents.

Mandibular repositioning appliances move the mandible and the associated structures like the tongue forward and prevent the tissues from collapsing during sleep.

A tongue retaining device in place holds the tongue in a forward position preventing it from falling backward and blocking the airway

## Diagnosis of Obstructive Sleep Apnea

Since OSA is a serious medical condition, it must be diagnosed by a physician. Diagnosis is based on the results of an overnight sleep study called a Polysomnogram (PSG). Other factors of determining OSA are patient evaluation and history.

## Treatment Options

Good sleep hygiene, weight loss and exercise are some helpful OSA treatments a patient can practice on their own. However, medical and dental treatments include Continuous Positive Airway Pressure, Oral Appliance Therapy and Surgery.

## Continuous Positive Airway Pressure (CPAP)

Continuous Positive Airway Pressure (CPAP) is pressurized air generated from a bedside machine. The air is delivered through a tube connected to a mask, covering the nose. The force of the pressurized air splints the airway open. The CPAP opens the airway like air into a balloon; when air is blown into the balloon it opens and gets wider. This is exactly how CPAP clears the airway.

## Oral Appliance Therapy ♦♦♦

Oral appliances are worn in the mouth to treat snoring and OSA. These devices are similar to orthodontic retainers or sports mouth guards. Oral Appliance Therapy involves the selection, design, fitting and use of a custom designed oral appliance that is worn during sleep. This appliance then attempts to maintain an opened, unobstructed airway in the throat. There are many different oral appliances available. Approximately 40 appliances have been approved through the FDA for treatment of snoring and/or sleep apnea. Oral appliances may be used alone or in combination with other means of treating OSA. These means include general health, weight management, surgery or CPAP.

Oral appliances work in several ways:

- Repositioning the lower jaw, tongue, soft palate and uvula
- Stabilizing the lower jaw and tongue
- Increasing the muscle tone of the tongue

Dentists with training in Oral Appliance Therapy are familiar with the various designs of appliances. They can determine which one is best suited for your specific needs. The dentist will work with your physician as part of the medical team in your diagnosis, treatment and on-going care.

Determination of proper therapy can only be made by joint consultation of your dentist and physician. Initiation of oral appliance therapy can take from several weeks to several months to complete. Your dentist will continue to monitor your treatment and evaluate the response of your teeth and jaws.

## Surgical Procedures ♦♦♦

In addition to Oral Appliance Therapy, dentists who are oral and maxillofacial surgeons may consider a variety of methods to evaluate, diagnose and treat upper airway obstruction. These dental specialists treat upper airway obstructive disorders by utilizing both minimally invasive procedures as well as more complex surgery, including jaw advancement. Additionally, an ENT specialist may evaluate you for other types of surgery, mainly the removal of the excess tissues in the throat. It may be necessary to remove tonsils and adenoids (especially in children), the uvula, or even parts of the soft palate and the throat.

## American Academy of Dental Sleep Medicine ♦♦♦

Your American Academy of Dental Sleep Medicine dentist and sleep physician will work together with you to determine the best course of therapy.

To learn more about dental sleep medicine, please talk to your dentist, physician or visit the American Academy of Dental Sleep Medicine Web site at [www.aadsm.org](http://www.aadsm.org).
